MAST30025: Linear Statistical Models
Assignment 1 S1 2021

Michael Le (998211)

March 23, 2021

Question 1 Solution:

Part a:

$A^2 = A^3$

Suppose A is a square matrix is (real and) symmetric then its eigenvalues are all real, and its eigenvalues are orthogonal.

***Theorem* 2.3**

Proof:

Take A to be a square matrix, n x n. First we diagonalise A,i.e., find P such that.

=

$$D = P^T AP$$

$$= \begin{bmatrix} \lambda_1 & .... & 0 \\ ...... & .... & .. \\ 0 & .... & \lambda_k \end{bmatrix}$$

where $\lambda_1, \lambda_2, ..., \lambda_k$ *are the eigenvalues of A.*

Since P is orthogonal both P and P^T *are non − singular,*

$$r(P^T AP) = r(p^T A) = r(A)$$

Because $P^T AP$ *is diagonal* $r(P^T AP)$ *is the number of non zero eigenvalues of A.*

But we wanted to prove ***Theorem* 2.2**

that A any symmetric matrix is idempotent. Which has eigenvalues of $\lambda = 0$ or $\lambda = 1$.

The eigenvalues of idempotent matrices are always either

$\lambda = 0$ or $= 1$.

$A^2 = \lambda^2$x

Multiplying by A!!!

A^3x $= A^2$ λx $= \lambda$ A^2x $= \lambda^3$ x

$(\lambda^3 - \lambda^2)\boldsymbol{x} = 0$

By definition, x$\neq 0$,

$\lambda^3 - \lambda^2 = 0$
$\lambda^2(\lambda - 1) = 0$

Therefore there are two values with eigenvalues of 0 and one eigenvalue of 1! satisfies this theorem that A is idempotent!

Part b:

$$A = A^3$$

A^3x = A λx = λ Ax = λ^3 x

Using the same theorem from the previous it has eigenvalues of 0,1 and -1. Since we care that A has to be positive semi-definite. Which has an eigenvalue of -1. Which does not satisfy Theorem 2.2! A is not idempotent!

Question 2 Solution:
Theorem 2.4

There exists a matrix **P** which diagonalises A_1**,....,**A_m.

$$P^T A_i P = D_i$$

and

$$P^T A_j P = D_j$$

We take A_i and A_j to be k x k matrices first we diagonalizes A_i, A_j, i.e. find P such that,

$D_i = P^T \ A_i$ P = $\begin{bmatrix} \lambda_1 & \ldots\ldots & 0 \\ \ldots\ldots\ldots & \lambda_2 & \ldots\ldots \\ 0 & \ldots\ldots\ldots & \lambda_k \end{bmatrix}$

for i = 1,.....,k

$D_j = P^T \ A_j$ P = $\begin{bmatrix} \lambda_1 & \ldots\ldots & 0 \\ \ldots\ldots\ldots & \lambda_2 & \ldots\ldots \\ 0 & \ldots\ldots\ldots & \lambda_m \end{bmatrix}$

for j = 1,.....,m

Proof:

P$^T A_i A_j P = (P^T A_i P)(P^T A_j P) = (P^T A_j P)(P^T A_i P) = P^T A_j A_i P$

Pre-multiply by P and post-multiply by P^T to get $A_i A_j = A_j A_i$.

Question 3 Solution:
Pre Proof Using Theorem 2.3
For any matrix A

$$r(A) = r(A^T) = r(A^T A) = tr(A)$$

A $= \begin{bmatrix} | & | & ...... & | & .... & | \\ a_1 & a_2 & .... & a_p & .... & a_n \\ | & | & ...... & | & .... & | \end{bmatrix}$

Given A matrix with dimensions n x p with p independent columns.
Let x$_1, x_2, x_3, ..., x_k$ *the basis for column space of A.*
Definition of basis every column vector of A is a linear combination of the column vectors of x.

$$a_1 = b_1 x_1 + b_2 x_2 + ... + b_k x_k$$

Definition of linear combination
where b is scalar

B $= \begin{bmatrix} --b_1-- \\ --b_2-- \\ | \\ --b_p-- \end{bmatrix}$

$$\begin{bmatrix} | & | & ...... & | & .... & | \\ a_1 & a_2 & .... & a_p & .... & a_n \\ | & | & ...... & | & .... & | \end{bmatrix} = \begin{bmatrix} | & | & ...... & | & .... & | \\ x_1 & x_2 & .... & x_p & .... & a_n \\ | & | & ...... & | & .... & | \end{bmatrix} \begin{bmatrix} --b_1-- \\ --b_2-- \\ | \\ --b_p-- \end{bmatrix}$$

$$A = XB$$

$$A^T = (XB)^T = B^T X^T$$

r(A) $\leq r(A^T)$ *or* $r(A) \geq r(A^T)$ *to satisfy*!

$$r(A) = r(A^T) = r(A^T A) = tr(A) = p$$

Since P is orthogonal both P and P^T are non-singular. Therefore we need to sum up the diagonal elements of P$^T AP$, *so we need to sum up its trace*!

$$r(A) = r(P^T AP) = tr(P^T AP) = tr(PP^T A) = tr(A) = p$$

Because D $= P^T$AP is diagonal r(P$^T AP$) *is the number of nonzero values of A*!
But A is idempotent so its takes eigenvalues between 0 or 1. To Prove Theorem 2.7! We need only the identity matrix to allow A^TA to be positive definite!

Using Theorem 2.7
Proof **($\Leftarrow$) :**

We want A^T*A to be symmetric*

and have all the eigenvalues to be strictly positive to prove $A^T A$ is a positive definite matrix!

we know r($A^T A$) = p is a p x p matrix so it has to be a full rank matrix, p!

Let,λ_1, λ_2,.....,$\lambda p > 0$ be the eigenvalues of A^TA for every x and for each eigenvalue has to have a value of 1.

for z = P^Tx = $(z_1, ..., zp)^T$

$$x^T(A^T A)x = x^T PDP^T x = z^T Dz = \sum_{i=1}^{p} z_i^2 \lambda_i$$

since λ_i = 1!

$$= \sum_{i=1}^{p} z_i^2$$

> 0

Thus $A^T A$ is positive definite as required!

Proof **($\Rightarrow$) :**

Suppose $A^T A$ is positive definite let x_i be its normalised i-th eigenvector then,

$$x_i^T(A^T A)x_i = \lambda_i x_i^T x_i = \lambda_i$$

From theorem 2.3 we want $A^T A$ to be symmetric and idempotent. We want the eigenvalues to be 0 or 1. This case all of the eigenvalues must equal to 1.

$\lambda_i = 1 > 0$

So, the eigenvalues of $A^T A$ are strictly positive as required!!

Question 4 Solution:

Part a:

Given information:

Let,

x_1,x_2,$x_3$$\sim$ ($N(\mu$,σ^2)) be a sequence of independent normal random variables,

$$\bar{x} = \frac{x_1 + x_2 + x_3}{3}$$

$\boldsymbol{x^T} = (x_1, x_2, x_3)^T$

Supposed to be x^T as noted!

$\boldsymbol{y}$ = (x$_1$ - ,x_2- ,x_3-)^T

To solve A from:

$$\boldsymbol{y} = A\boldsymbol{x}$$

$$\begin{bmatrix} x_1 - \bar{x} \\ x_2 - \bar{x} \\ x_3 - \bar{x} \end{bmatrix} = \frac{1}{3}\begin{bmatrix} 2 & -1 & -1 \\ -1 & 2 & -1 \\ -1 & -1 & 2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}$$

A $= \frac{1}{3}\begin{bmatrix} 2 & -1 & -1 \\ -1 & 2 & -1 \\ -1 & -1 & 2 \end{bmatrix}$

Where A is symmetric and idempotent!

$A^2 = \frac{1}{9}\begin{bmatrix} 6 & -3 & -3 \\ -3 & 6 & -3 \\ -3 & -3 & 6 \end{bmatrix} = \frac{1}{3}\begin{bmatrix} 2 & -1 & -1 \\ -1 & 2 & -1 \\ -1 & -1 & 2 \end{bmatrix} =$ A

Part b: Finding the rank of A

Proof: that there is a linear combination for any columns?

```{r}
A = matrix(c(2,-1,-1,-1,2,-1,-1,-1,2)/3,3,3)
```

```
           [,1]       [,2]       [,3]
[1,]  0.6666667 -0.3333333 -0.3333333
[2,] -0.3333333  0.6666667 -0.3333333
[3,] -0.3333333 -0.3333333  0.6666667
```

```
# Finding rank of A
```

```{r}
rankMatrix(A)[1]
```

```
[1] 2
```

Each column all added up together gives us 0!.

x$_1 + x_2 + x_3 = 0$

Can be written as,
$x_1 = -x_2 - x_3$
That are linearly dependant and similar for $x_2 and x_3$
Hence r(A) = 2

Part c: Computing E[$y^T y$]
Using Theorem 3.5:
E[$y^T Ay] = tr(AV) + \mu^T A\mu$
since A = I,
= tr(V) + $\mu^T \mu$
V = vary = varAx = AvarxA^T
since A is symmetric and idempotent!!

$$\text{var}(x_i) = \begin{bmatrix} \sigma^2 & 0 & 0 \\ 0 & \sigma^2 & 0 \\ 0 & 0 & \sigma^2 \end{bmatrix}$$

$$V = \frac{1}{3} \begin{bmatrix} 2\sigma^2 & -1 & -1 \\ -1 & 2\sigma^2 & -1 \\ -1 & -1 & 2\sigma^2 \end{bmatrix}$$

$\mu = E[y] = E[Ax] = AE[x]$

$$= \frac{1}{3} \begin{bmatrix} 2 & -1 & -1 \\ -1 & 2 & -1 \\ -1 & -1 & 2 \end{bmatrix} \begin{bmatrix} \mu \\ \mu \\ \mu \end{bmatrix} = 0$$

$$E[y^T y] = tr(\frac{1}{3} \begin{bmatrix} 2\sigma^2 & -1 & -1 \\ -1 & 2\sigma^2 & -1 \\ -1 & -1 & 2\sigma^2 \end{bmatrix}) + 0$$

$= 2\sigma^2$
Part d:
Using Theorem 3.5:
Proof:

Assuming that A is idempotent and has rank k. Because it is symmetric, it can be diagonalised. Let the (orthogonal) diagonalising matrix be P.

$$D = P^T AP = \begin{bmatrix} \lambda_1 & ...... & 0 \\ .... & \lambda_2 & ...... \\ 0 & .... & \lambda_k \end{bmatrix}$$

since A is symmetric and idempotent, all eigenvalues are either 0 or 1. We know from definition:

$$tr(A) = r(A) = k$$

A $=\frac{1}{3}\begin{bmatrix} 2 & -1 & -1 \\ -1 & 2 & -1 \\ -1 & -1 & 2 \end{bmatrix}$

A^2 = A = $\frac{1}{3}\begin{bmatrix} 2 & -1 & -1 \\ -1 & 2 & -1 \\ -1 & -1 & 2 \end{bmatrix}$

from Part 4b, we find out the rank and trace of matrix A we found in Part 4a. Is also is the same number of degrees of freedom for the chi squared distribution.

$$tr(A) = r(A) = 2$$

Therefore, A must have two eigenvalues of 1 and one eigenvalue of 0.

Using Theorem 3.5 and Corollary 3.7:

with our non central parameter λ!

$\lambda = \frac{1}{2}\mu^T A\mu$

$= \frac{1}{2}\begin{bmatrix} \mu & \mu & \mu \end{bmatrix} \frac{1}{3}\begin{bmatrix} 2 & -1 & -1 \\ -1 & 2 & -1 \\ -1 & -1 & 2 \end{bmatrix} \begin{bmatrix} \mu \\ \mu \\ \mu \end{bmatrix}$

$= 0$

$\iff$: *if and only if*

E[y] = E[$\begin{bmatrix} x_1 - \mu \\ x_2 - \mu \\ x_3 - \mu \end{bmatrix}$]

Since x_1, x_2 *and* x_3 *is identically independently distributed*! *and taking* the expectation of the expectation is the expectation itself!

E[y] = E[$\begin{bmatrix} \mu - \mu \\ \mu - \mu \\ \mu - \mu \end{bmatrix}$] = 0

NOTE: $\mu = \bar{x}$

In which case,

$\frac{y^T y}{\sigma^2}$

is just the sum of two independent standard normal's. This is just an ordinary (central) chi squared distribution χ^2_2.

with expectation of 2 and variance of 4 with 2 degrees of freedom. In which A is symmetric and idempotent!

Question 5 Solution:

Part a: Computing y,X,β and ϵ

$$\boldsymbol{y} = \begin{bmatrix} 27.3 \\ 42.7. \\ 38.7 \\ 4.5 \\ 23.0 \\ 166.3 \\ 109.7 \\ 80.1 \\ 150.7 \\ 20.3 \\ 189.7 \\ 131.3 \\ 404.2 \\ 149 \end{bmatrix}. \quad \boldsymbol{X} = \begin{bmatrix} 1 & 13.1 \\ 1 & 15.3 \\ 1 & 25.8 \\ 1 & 1.8 \\ 1 & 4.9 \\ 1 & 55.4 \\ 1 & 39.3 \\ 1 & 26.7 \\ 1 & 47.5 \\ 1 & 6.6 \\ 1 & 94.7 \\ 1 & 61.1 \\ 1 & 135.6 \\ 1 & 47.6 \end{bmatrix} \quad \boldsymbol{\beta} = \begin{bmatrix} \beta_0 \\ \beta_1 \end{bmatrix} \quad \boldsymbol{\epsilon} = \begin{bmatrix} \epsilon_0 \\ \epsilon_1 \\ \epsilon_2 \\ \epsilon_3 \\ \epsilon_4 \\ \epsilon_5 \\ \epsilon_6 \\ \epsilon_7 \\ \epsilon_8 \\ \epsilon_9 \\ \epsilon_{10} \\ \epsilon_{11} \\ \epsilon_{12} \\ \epsilon_{13} \end{bmatrix}$$

$\boldsymbol{y} = \boldsymbol{X\beta} + \boldsymbol{\epsilon}$ *becomes,*

$$\begin{bmatrix} 27.3 \\ 42.7. \\ 38.7 \\ 4.5 \\ 23.0 \\ 166.3 \\ 109.7 \\ 80.1 \\ 150.7 \\ 20.3 \\ 189.7 \\ 131.3 \\ 404.2 \\ 149 \end{bmatrix}. = \begin{bmatrix} 1 & 13.1 \\ 1 & 15.3 \\ 1 & 25.8 \\ 1 & 1.8 \\ 1 & 4.9 \\ 1 & 55.4 \\ 1 & 39.3 \\ 1 & 26.7 \\ 1 & 47.5 \\ 1 & 6.6 \\ 1 & 94.7 \\ 1 & 61.1 \\ 1 & 135.6 \\ 1 & 47.6 \end{bmatrix} \begin{bmatrix} \beta_0 \\ \beta_1 \end{bmatrix} \quad + \quad \begin{bmatrix} \epsilon_0 \\ \epsilon_1 \\ \epsilon_2 \\ \epsilon_3 \\ \epsilon_4 \\ \epsilon_5 \\ \epsilon_6 \\ \epsilon_7 \\ \epsilon_8 \\ \epsilon_9 \\ \epsilon_{10} \\ \epsilon_{11} \\ \epsilon_{12} \\ \epsilon_{13} \end{bmatrix}$$

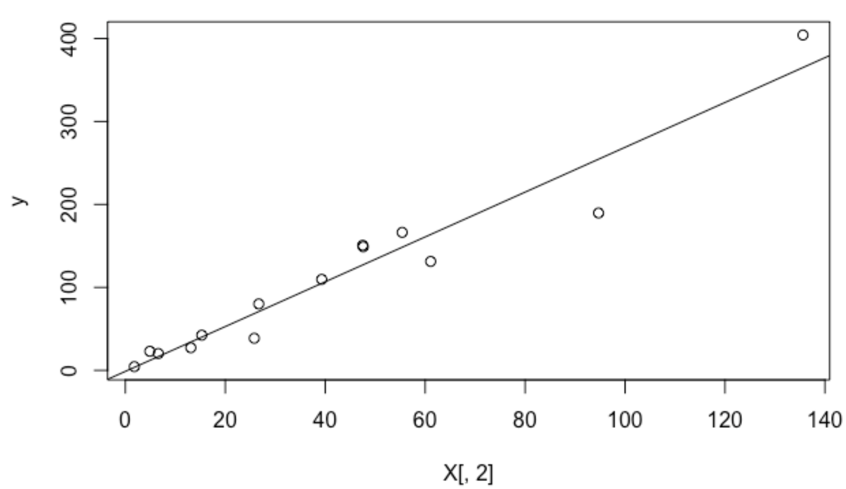
Part g:

```{r}
plot(X[,2],y)
abline(b[1],b[2])

```



Full explaination: The Cook's distance certainly indicates it should be of some concern; however looking at the plot, it seems that the fit is actually okay. There is considerable evidence for heteroskedasticity — the variance increases with x (the design variable). Sea scallops has (by far) the largest x and so may be prone to a larger variance than the remaining points. The high Cook's distance therefore comes primarily from a very high leverage, rather than a bad fit to the model.

END OF ASSIGNMENT!!
