MAST30027: Modern Applied Statistics

Week 3 Lab

1. The binomial random variable $Y \sim bin(m, p)$ for known m (not a parameter) has mass function:

$$f(y;p) = {m \choose y} p^y (1-p)^{m-y}$$
 for $y = 0, 1, \dots, m$.

Show that the binomial distribution is an exponential family.

Solution:

$$f(y) = \binom{m}{y} p^y (1-p)^{m-y} \text{ for } y = 0, 1, \dots, m$$

$$= \exp\left[y \log \frac{p}{1-p} + m \log(1-p) + \log \binom{m}{y}\right]$$

$$= \exp\left[\frac{y\theta - b(\theta)}{a(\phi)} + c(y, \phi)\right]$$

where $\theta = \log \frac{p}{1-p}$, $\phi = 1$, and

$$b(\theta) = -m \log(1 - p)$$

$$= -m \log \left(\frac{1}{1 + e^{\theta}}\right)$$

$$= m \log(1 + e^{\theta})$$

$$a(\phi) = \phi$$

$$c(y, \phi) = \log \binom{m}{y}$$

2. The infert dataset from the survival package presents data from a study of infertility after spontaneous and induced abortion. You can load the dataset using the following command.

```
library(survival)
data(infert)
?infert
str(infert)
```

The response is **case**, with 1 indicating infertility and 0 fertility. The data comes from a case-control study, the aim of which was to estimate the effect of the number of prior induced and spontaneous abortions on the probability of becoming infertile. We will consider education, age and parity (something numeric, whatever it is) as other predictors.

Fit a binomial regression model with case as a response variable and induced (the number of prior induced abortions), spontaneous (the number of prior spontaneous abortions), education, age and parity as predictors. Test whether the education is important to predict the probability of becoming infertile when all other predictors are in the model.

Solution We will perform LRT using difference in scaled deviance.

```
glm(formula = case ~ age + parity + education + spontaneous +
   induced, family = binomial(), data = infert)
Deviance Residuals:

> pchisq(deviance(model2) - deviance(model1), 2, lower.tail=FALSE)
```

Call:

[1] 0.2074555

The pvalue is bigger than 0.05, so the education is not important to predict the probability of becoming infertile when all other predictors are in the model.

3. The dataset discoveries lists the number of great scientific discoveries for the years 1860 to 1959, as chosen by "The World Almanac and Book of Facts", 1975 Edition. Has the discovery rate remained constant over time?

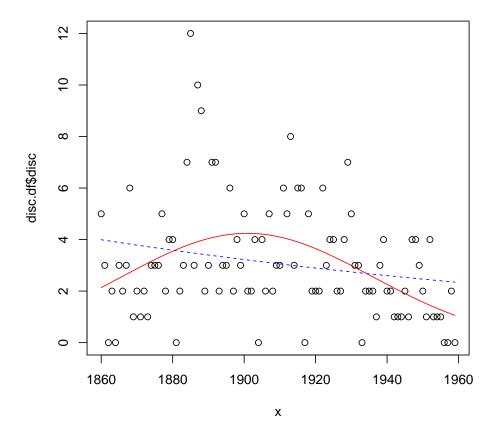

To answer this question, fit a poisson regression model with a log link, and use the deviance to compare a null model with models including the year and year squared as predictors.

Load the dataset using the command data(discoveries).

Solution First we fit two models, the first including the year and the second the year and the year squared. The plot gives the fitted rates in each case.

```
> data(discoveries)
> disc.df <- data.frame(year=1860:1959, disc=discoveries)</pre>
> model1 <- glm(disc ~ year, family=poisson, disc.df)</pre>
> summary(model1)
Call:
glm(formula = disc ~ year, family = poisson, data = disc.df)

> lines(x, exp(beta1[1] + beta1[2]*x), col="blue", lty=2)
> beta2 <- model2$coefficients
> lines(x, exp(beta2[1] + beta2[2]*x + beta2[3]*x^2), col="red")
```

We will use deviance differences to perform likelihood ratio tests. From the above, the null model has deviance 164.68, the model with just year has deviance 157.32, and the model with year and year squared has deviance 132.84. We compare the null model with the model with year, and the model with year and year squared. We also compare the model with year with the model with year and year squared.

```
> pchisq(164.68-157.32, 1, lower.tail=FALSE)
```

[1] 0.006669079

> pchisq(164.68-132.84, 2, lower.tail=FALSE)

[1] 1.219079e-07

> pchisq(157.32-132.84, 1, lower.tail=FALSE)

[1] 7.508521e-07

There is strong evidence that year improves the model, and very strong evidence that year squared has something to add. We conclude that there is strong evidence that the discovery rate has changed over time.
